THIS PAGE IS INTENTIONALLY BLANK

1.0 Executive Summary

This report presents a summary of the annual inspection for the Grand River Dam Authority (GRDA) Coal Combustion Residual (CCR) landfill at the Grand River Energy Center (GREC) in Chouteau, Oklahoma. The annual inspection was completed by Black & Veatch on December 6, 2022. The annual inspection was completed in compliance with Oklahoma Administrative Code (OAC) 252:517-13-5 *Inspection Requirements for CCR Landfills*.

Requirements in 252:517-13-5 include review of available information regarding the landfill as well as a visual inspection of the landfill and appurtenant structures.

1.1 SUMMARY OF FINDINGS

Inspection of the CCR landfill did not identify any signs of structural weakness or conditions that would disrupt or affect the safety of the landfill. There were no current concerns with existing conditions or the existing maintenance.

1.2 RECOMMENDATIONS

Based on the results of the inspection, Black & Veatch has no recommendations for improvements, no concerns for stability, and no recommendations for changes in the maintenance program.

2.0 Inspection Team and Date of Inspection

2.1 INSPECTION TEAM

The inspection team consisted of three GRDA employees and one Black & Veatch geotechnical engineer. The inspection team members included:

Michael Bednar
Grand River Dam Authority
Manager of Environmental
Compliance (918) 824-7565
Mike.Bednar@grda.com

Aaron Hester
Grand River Dam Authority
Environmental Compliance
Aaron.Hester@grda.com

Steve Jacoby; P.E., S.E.
Grand River Dam Authority
V.P. President Generation
Support and Engineering
(918)-610-9727
Steve.Jacoby@grada.com

Gary Sommerfeld, P.E.
Black & Veatch
Geotechnical Engineer
(913) 458- 9319
sommerfeldg@bv.com

2.2 DATE OF INSPECTION

The inspection team began their work at 10:15 a.m. on Tuesday, December 6, 2022 and completed their work at 12:15 p.m.

2.3 WEATHER DURING INSPECTION

The weather on the day of the inspection was cloudy, slight wind, with an ambient temperature about 40° Fahrenheit. There had been no significant precipitation within the previous week but there was light rain previously to the inspection on the day of the investigation.

3.0 Description of Landfill

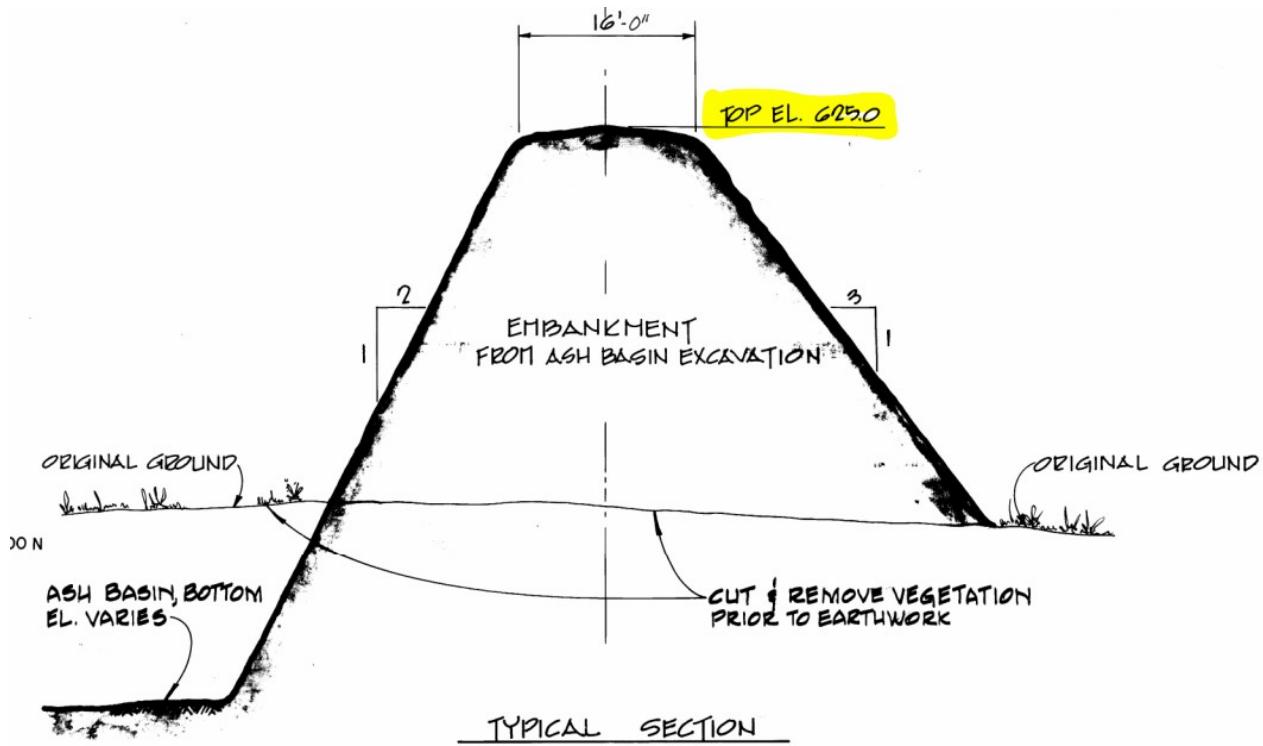

3.1 GENERAL DESIGN INFORMATION

The GREC power plant is located east of Chouteau within Mayes County, in northeastern Oklahoma. It was designed with a 490 MW Unit that was commissioned in 1981. The facility expanded operations in 1985 with a second unit rated at 520 MW. Unit 2 has a dry Flue Gas Desulfurization(FGD) scrubber for control of sulfur emissions.

The GREC landfill was permitted in 1979 as a Non-Hazardous Industrial Waste Landfill that is allowed to accept fly ash, bottom ash and spent powdered activated carbon used to control flue gas emissions, generated at the GREC facility. The original permitted landfill consisted of 116 acres, of which only 47 acres have been utilized for placement of CCR materials.

In October 2017, a request to modify the existing landfill permit was submitted to DEQ. The modification requested a reduction in landfill permit area from 116 acres to 67 acres. The request for permit modification has been approved by DEQ. The original drawings for the landfill were completed in 1979 by Holway-United. The drawings show the embankments surrounding the landfill were constructed to Elevation 625 with a 16-foot wide top and 2 Horizontal to 1 Vertical side slopes, see Figure 3-1. Soil materials from inside the landfill area were used to construct the embankments.

The landfill was designed so that all surface water drainage is routed around the landfill area and into a series of permitted Class III industrial wastewater treatment impoundments regulated under an Oklahoma Pollutant Discharge Elimination System (OPDES) permit OK0035149. The industrial wastewater system consists of 11 process water and storm water retention/treatment basins around the western and southern perimeter of the landfill. These surface impoundments provide a total holding capacity of 1,371,521,000 gallons as stated in the facility OPDES permit and receive process water, cooling tower water, and storm water run-off from the landfill, coal pile, and the operational areas of the plant. The discharge is to the Neosho River.

Figure 3-1 Original Design Drawing Cross-Section of Landfill Embankment

3.2 OPERATIONS

Disposal operations within the power plant require dump trucks to haul the fly ash and bottom ash from the plant to the landfill. The haul trucks are loaded from storage silos using dry disposal methods. The haul trucks unload the ash in the landfill area and dozers are used to grade the material into even lifts. A water truck is used to condition the dry ash to aid in grading and prevent fugitive dust. Currently the existing face of the disposed ash is on the north and the drainage of the exposed ash is toward the north. In general, bottom ash is deposited at the northeast corner of the current working face of the landfill area. The bottom ash has occasionally been sold as a beneficial use product; therefore, bottom ash is deposited separately from the fly ash. Bottom ash has a granular/gravel texture and is also dampened with water for fugitive dust control purposes prior to loading. Once loaded, the transport vehicles then convey CCRs to the landfill for final disposal. At the landfill, water trucks are used to minimize fugitive dust as necessary. Ash material that has been placed at the planned final grade has been capped with the planned cover soil, topsoil and seeded with grass.

During the past year, the bottom ash has been consolidated toward the north end to provide better conditions for deposition of fly ash. The bottom ash has been directed toward the north and east of the active open area. The work over the year has continued grading and capping the top of the landfilled area.

The modification of the east perimeter and construction of the new east embankment had started during this year and is partially complete. The regrading of the east side of the landfill has been part of the east embankment construction.

The completed portions of the landfill still maintain a good stand of grass and has been maintained by mowing. There was no indication of new growth within older vegetation indicating that the grass and vegetation has been uniformly maintained with no signs of bare patches or seeps. No ruts or erosion rills were observed on the side slopes.

Grading and CCR deposition are constant on the north portion of the landfill area. Fly ash and bottom ash are deposited separately but within the same general landfill area.

3.3 LANDFILL VOLUME AND CAPACITY

Based on the original construction drawings, the landfill's exterior embankment was constructed to elevation 625 feet. CCR materials have been placed in the west 47 acres of the original permitted landfill boundary. Side slopes of the landfilled ash (ash deposited inside the embankments) have been graded at 4 horizontal to 1 vertical in compliance with the Closure Plan, dated February 22, 2018.

The most recent survey evaluation of ash placement has estimated the current ash volume to be 3,765,300 cubic yards within the 47 acre footprint.

Construction of the new embankment is on the east side of the active 47 acre landfilled area. This will reduce the permit area to the current footprint of stored ash materials. Using the planned closure grades and elevations for the 47 acres, the planned capacity of the landfill area will be 4,350,000 cubic yards.

3.4 LANDFILL INSPECTION PROCEDURES

In accordance with OAC 252:517-13-5(a)(1) the facility is inspected on a weekly basis by plant personnel. The inspections include observations of structural integrity, fugitive dust, and proper operations. The inspection findings and any required actions are recorded and presented at <https://www.grda.com/ccr-weekly-ccr-landfill-inspection-for-2022/>

The weekly inspections were initiated on October 11, 2015. The weekly inspection reports have been completed during the past year and were reviewed for this inspection.

4.0 Inspection Findings

Black & Veatch completed the annual inspection based on the requirements of OAC 252:517-13-5(b) *Annual Inspection by a Qualified Professional Engineer*. The inspection was completed as a visual inspection with the main goals of identifying signs of distress or malfunction of the embankments and cover soils. As part of this inspection, Black & Veatch also performed a review of the available information which included the following documents;

- a. Coal Combustion Residual (CCR) Landfill – Stability Analysis Report, prepared by Black & Veatch, 9 July 2020.
- b. Grand River Dam Authority (GRDA) 490-MW Coal Fired Generating Station Ash Disposal Permit Application, Chouteau, Oklahoma; 22 August 1979.
- c. Oklahoma Administrative Code (OAC). Chapter 517. Disposal of Coal Combustion Residuals from Electric Utilities, Effective 15 September 2018
- d. Bottom Ash Surface Impoundment Hazard Potential Classification Assessment, prepared by Black & Veatch, October 2016.
- e. Closure Plan for GRDA Landfill – Grand River Energy Center, by A & M Engineering and Environmental Services, Inc, 22 February 2018.
- f. Quality Assurance and Quality Control Plan for GRDA Landfill – Grand River Energy Center, by A & M Environmental Services, 13 September 2019.
- g. CCR Weekly Landfill Inspection Report for 2022. grda.com/ccr-weekly-ccr-landfill-inspection-for-2022/

Field inspection of the landfill included a site walk to observe the embankment crest, embankment slope, embankment toe, and cover soils.

4.1 RESULTS OF INSPECTION

4.1.1 Crest

The crest of the landfill embankments on the south, west, and north sides are grass covered. The crest of the embankments had good grass cover, no signs of cracking, settlement, movement, erosion, or deterioration. (See Figure 4-1). Mowing operations have maintained a good height for the grass and no unwanted vegetation (bushes or trees) were observed. No ruts or bare areas were observed on the crest. No depressions or slumps were observed that would indicate the beginnings of slope failure. There were no erosion areas that could not be traversed by the mowing equipment and there were no apparent wet areas on the slopes.

Figure 4-1 – Crest of West Embankment, Center Looking North.

The crest of the embankment on the south side of the landfill had been covered with ash and the crest was not distinguishable along the side slope. The original permitted landfill embankments to the northeast and east have been stripped of topsoil and has been used as cover soil on the final grades of the CCR material.

The east half of the landfill south embankment has some overgrowth vegetation, but this embankment has never retained CCR material. The northeast, east, and southeast permitted embankments will be removed from the permitted landfill area when a new east embankment is constructed adjacent to the existing ash material.

4.1.2 Exterior Slopes - Embankment

The exterior slopes of stockpiled CCR were capped with the cover soil, topsoil, and vegetation. There were no signs of unwanted vegetative growth, new encroachments, or settlement. There were no active erosion channels along the slopes. There were no erosion channels too deep for access by the mowing equipment. No wet or damp areas were observed that would indicate seepage. The grass has prevented active erosion.

Figure 4-2 – South CCR Slope and Embankment with Vegetation Cover. East Looking West.

There was no indication that some sod cover had more growth due to higher moisture contents. There were no signs of slope stability problems and no signs of depression caused by slumping ground.

There was no indication of animal burrows or animal tracks leading to burrows. As stated in the weekly reports there are no observed animal encroachments in the embankment materials.

4.1.3 Exterior Slopes – CCR Material

The areas of the CCR material that have reached final grade have been capped with the planned cover soil, topsoil, and grass seed. In general, the cover soil observed on the closed portion of the landfill was the same condition as the exterior slopes of the embankment. Areas of the south CCR landfill have grass cover on areas that are not yet fully closed. The grass cover provides runoff and erosion protect. This is observed on the east side of the CCR material adjacent to the new

embankment that under construction (Figure 4-3)

Figure 4-3 East CCR material with new embankment construction, South Looking North

Figure 4-3 Final Cover on top of CCR Material – Top of Landfill from Center looking Southwest

The top surface of the landfill area has been graded to slope toward the north and the area has been covered with the planned cover soils, topsoil, and vegetation. The areas that had been vegetated within the past year were not discernable from older areas indicated good growth and appropriate mowing that limits brush and trees.

5.0 Conclusions and Recommendations

Based on the landfill embankments and final grading of the CCR material as observed during the inspection on December 6, 2022, the landfill is considered sufficient to function as intended.

There were no signs of distress or instability problems associated with the landfill embankments or stored CCR materials.

There are no recommendations for the future of the landfill or the related structures.
